How Bacteria Talk to Each Other

Martin J. Blaser
A Mixed Bag: Bacteria That Colonize Humans
Instructions for Authors

**IN VIVO** is published three times yearly during the Fall, Winter, and Spring. Original research articles in the field of biology in addition to original articles of general interest to faculty and students may be submitted to the editor to be considered for publication. Manuscripts can be in the form of a) full length manuscripts, b) mini-reviews or c) short communications of particularly significant and timely information. Manuscripts will be evaluated by two reviewers.

Articles can be submitted electronically to invivo@mec.cuny.edu or mailed as a printed copy (preferably with a diskette that contains the file) to the Editorial Board at Medgar Evers College. All submissions should be formatted double spaced with 1 inch margins. The title of the article, the full names of each author, their academic affiliations and addresses, and the name of the person to whom correspondence should be sent must be given. As a rule, full length articles should include a brief abstract and be divided into the following sections: introduction, materials and methods, results, discussion, acknowledgments and references. Reviews and short communications can be arranged differently. References should be identified in the text by using numerical superscripts in consecutive order. In the reference section, references should be arranged in the order that they appeared in the text using the following format: last name, initials., year of publication. title of article, journal volume number: page numbers. (eg. - "Hassan, M. and V. Herbert, 2000. Colon Cancer. **In Vivo** 32: 3 - 8). For books the order should be last name, initial, year of publication, title of book in italics, publisher and city, and page number referred to. (eg. - Prosser, C.L., 1973. *Comparative Animal Physiology*, Saunders Co., Philadelphia, p 59.). Abbreviations and technical jargon should be avoided. Tables and figures should be submitted on separate pages with the desired locations in the text indicated in the margins.

Seton Hall University was founded in 1856 by Bishop James Roosevelt Bayley, the first bishop of Newark. It is the oldest diocesan university in the United States.

Nestled on 58 acres in the suburban village of South Orange, NJ, the campus is home to eight schools and colleges: the College of Arts and Sciences, the College of Education and Human Services, the College of Nursing, the John C. Whitehead School of Diplomacy and International Relations, the School of Health and Medical Sciences, the Stillman School of Business, and the Immaculate Conception Seminary School of Theology. Seton Hall’s eighth school, the School of Law, is located in Newark, New Jersey. The Division of Continuing Education and Professional Studies is located on the South Orange Campus.

Seton Hall University is founded on and defines itself and its academics, student life and community programs on a Christian understanding of the nature of the world and the human person. With a tradition of quality education based on Christian values, the University takes pride in its concern for the intellectual, ethical and spiritual development of its undergraduate and graduate students.

Seton Hall is committed to bringing together people of different races, cultures, religious traditions, lifestyles and ethnic backgrounds into a community that is respectful and supportive. This commitment has helped to establish a truly multicultural community in which all people of good will are welcome. Seton Hall strives to develop the intellectual, social and religious talents of its students so they may live their lives responsibly, generously and successfully.

At the undergraduate level, Seton Hall offers more than 60 majors and concentrations, as well as many minors, certificates, and interdisciplinary and other special programs.

The Department of Biological Sciences offers programs of study leading to the Bachelor of Arts, Bachelor of Science, Master of Science in Biology, Master of Science in Biology with a Business Administration minor, Master of Science in Microbiology, and Doctor of Philosophy in Molecular Bioscience. The Department of Biological Sciences also offers three dual degree programs: Physical Therapy (B.S./D.P.T.), Physician Assistant (B.S./M.S.P.A.), and Athletic Training (B.S./M.S.A.T.) with the School of Health and Medical Sciences. At the undergraduate level, the Department of Biological Sciences also offers an interdisciplinary minor program in environmental sciences.
Bactericidal Activity of L-carnitine Against Salmonella enterica Serovar Typhimurium

Abstract

The antimicrobial activity of L-carnitine against Salmonella enterica serovar Typhimurium was evaluated using minimum inhibitory concentration (MIC) and kill curve assays. The MIC for this quaternary ammonium compound was determined to be 3.125 mg/mL. Kill curve assays were conducted by exposing 10⁹ cfu/mL of S. enterica Typhimurium to L-carnitine at MIC, double MIC (6.25 mg/mL), and half MIC (1.525 mg/mL) and monitoring viable cell count over time. Results revealed a dose-dependent relationship between L-carnitine concentration and the rate of bactericidal activity. These data indicate that L-carnitine, a food additive that is generally regarded as safe (GRAS), can potentially be employed to reduce S. enterica Typhimurium.

Introduction

The proliferation and dissemination of antibiotic-resistant bacteria poses a significant threat to human health. Antimicrobial resistance is a natural consequence of the overuse of antimicrobial agents in medicine, agriculture, and the home1-5. The declining efficacy of conventional therapeutic antimicrobial agents makes infection control difficult and expensive6,7. Therefore, new compounds must be assessed for their antimicrobial properties and potential utility.

Carnitine is a quaternary ammonium compound biosynthesized from the amino acids lysine and methionine8. Like amino acids, the L isomer of carnitine is more relevant in biological systems. It was originally found to be a growth factor for mealworms and was categorized as vitamin BT9. Today, L-carnitine is marketed as a nutritional supplement and is a common component in energy drinks. During beta-oxidation, L-carnitine is utilized by eukaryotic cells for the transport of fatty acids from the cytosol into the mitochondria via the carnitine shuttle10-12. In addition, carnitine has osmoprotectant properties by acting as a compatible solute in bacteria13. L-carnitine also plays a role in sperm motility and energy production and helps provide a pathogen free environment in the male urogenital tract14.

Quaternary ammonium compounds are potent antimicrobials; they are colorless, unscented, flavorless, stable, easily diluted and non-toxic to tissue15. These compounds disrupt cell membranes and denature proteins and are effective against vegetative bacterial cells, protozoa, fungi, and enveloped viruses15. They are far less effective against spores and non-enveloped viruses16.

Quaternary ammonium compounds cause a dissociation of membrane phospholipid bilayers, directly affecting membrane permeability and resulting in leakage of cellular contents16. In addition, many enzymes involved with respiratory and metabolic cellular processes are denatured by quaternary ammonium compounds. Cationic quaternary ammonium compounds disrupt critical intermolecular protein interactions causing loss of tertiary structure.

Despite the routine use of some quaternary ammonium compounds as disinfectants, relatively little information is known about L-carnitine’s antimicrobial properties. One report noted that L-carnitine has antimicrobial activity against an array of Gram-positive and Gram-negative bacteria17. Another study found that a broad variety of modified L-carnitine esters had antimicrobial activity against the Gram-positive species Staphylococcus aureus and Enterococcus faecalis, and the Gram-negative species Escherichia coli and Proteus vulgaris18. In another study, acetyl-L-carnitine (ALC), a derivative of L-carnitine, was administered to patients with active pulmonary tuberculosis19. The study reported no
decline in pulmonary tubercles over a thirty day period when compared to a placebo group. *Salmonella*, a bacterial genus within family Enterobacteriaceae, is comprised of Gram-negative, rod-shaped, motile, facultative anaerobes that produce H₂S and do not ferment lactose. *Salmonellae* live in the intestinal tracts of warm and cold blooded animals. Some species, including *Salmonella enterica* serovar Typhimurium (*Salmonella* Typhimurium), cause an acute gastrointestinal illness called salmonellosis. In recent years, problems connected to *Salmonella* have amplified considerably, both in incidence and severity of disease. Moreover, there has been an increased rate of antibiotic-resistant *Salmonella* infections in the United States, including outbreaks of multidrug resistant (MDR) *Salmonella Typhimurium*. In this study, we focus on the antibacterial properties of L-carnitine against *Salmonella Typhimurium*.

**Materials and Methods**

**Culture conditions:** *Salmonella Typhimurium* cultures were maintained in autoclave-sterilized nutrient broth (Difco) at 37°C with agitation (sub-cultured every 24 hours). Overnight cultures (37°C, 24 hours, with agitation) were used as inocula for the following experiments.

**L-Carnitine stock solutions:** Stock solutions containing 100 mg/mL (10% [w/v]) L-carnitine were prepared by adding 5 g of L-carnitine to 45 ml of de-ionized water. L-Carnitine was put into solution by gentle warming on a stir plate. The solution was sterilized by vacuum filtration through a 0.22 μm pore size membrane filter (Millipore).

**Minimum inhibitory concentration (MIC):** Inocula were prepared by adding an overnight culture of *Salmonella Typhimurium* (37°C, 24 hrs, with agitation) to fresh nutrient broth to a final cell density of 10⁶ cfu/mL. One hundred μL of inoculated nutrient broth was added to the wells of a 96-well plate (Thermo Scientific). Two-fold serial dilutions of L-carnitine were made by adding 100 μL of the sterile 100 mg/mL aqueous L-carnitine solution to the first well of each inoculated row on the 96-well plate (final concentration = 50 mg/mL) and serially transferring 100 μL down the 14 cell row. The final dilution contained 0.0061 mg/mL of L-carnitine. To discount osmotic inhibition by L-carnitine at higher concentrations, MIC experiments were repeated using the amino acid glycine as a control. A negative control containing only inoculated nutrient broth was also performed. The 96-well plates were incubated at 37°C for 24 hrs and growth was assessed via optical density measurements using a microplate reader (595 nm wavelength) (Bio Rad).

**Results**

**Minimum inhibitory concentration (MIC):** The MIC for L-carnitine against *Salmonella Typhimurium* was determined to be 3.125 mg/mL. The MIC was also determined using glycine as a control to rule out osmotic inhibition as the mechanism of action for L-carnitine inhibition. The MIC for glycine was determined to be 25 mg/mL. Negative controls showed no inhibition at any point.

**Bactericidal curves:** A washed cell inoculum was created by adding an overnight culture of *Salmonella Typhimurium* (37°C, 24 hrs, with agitation) to 250 mL of fresh nutrient broth and the culture was incubated at 37°C for 150 minutes with agitation. Ten mL of the culture was added to sterile 15-mL conical centrifuge tubes (Falcon) and the tubes were centrifuged at 4,100 rpm for 10 minutes at 4°C. Cell pellets were washed with 10 mL of sterile phosphate buffered saline (PBS), re-centrifuged (4,100 rpm, 4°C, 10 minutes) and re-suspended in PBS to a final cell density of 10⁹ cfu/mL. Sterile aqueous L-carnitine was added to the PBS cell suspensions at 1.625 mg/mL (half the determined MIC for L-carnitine against *Salmonella Typhimurium* [see results]), 3.125 mg/mL (MIC), and 6.25 mg/mL (double the MIC). A negative control containing *Salmonella Typhimurium* with no L-carnitine was also prepared. Tubes were incubated at 37°C with agitation and optical density (595 nm wavelength) and viable cell counts were determined every 30 minutes for 120 minutes. In addition, the optical density and viable cell count was determined after 18 hours at 37°C with agitation.

**Statistical analyses:** All experimental determinations were performed in triplicate. If the coefficient of variation was < 10% and the difference among treatment means was large, statistics were not reported.
This work demonstrates that L-carnitine has antimicrobial effects against Salmonella Typhimurium. The MIC for L-carnitine against Salmonella Typhimurium was determined to be 3.125 mg/mL. To discount osmotic effects, an MIC was also determined using the simple amino acid glycine. The MIC for glycine against Salmonella Typhimurium was found to be 25 mg/mL (2.5% [w/v]), which is almost an order of magnitude higher than the MIC observed for L-carnitine. This suggests that inhibition of Salmonella Typhimurium by L-carnitine is not simply a result of hypertonicity.

A kill curve demonstrated the bactericidal effect of L-carnitine against $10^9$ cfu/mL of Salmonella Typhimurium (Figure 1). The results clearly show that 6.25 mg/mL (double the MIC) had the greatest bactericidal effect over the course of the 120 minute incubation. Treatment with the MIC concentration (3.125 mg/mL) and half the MIC (1.525 mg/mL) also displayed inhibitory properties, but caused a viable cell reduction that was 5 orders of magnitude less lethal than double MIC. These results show that L-carnitine inhibits Salmonella Typhimurium in a dose-dependent manner.

The chemical structure of L-carnitine differs somewhat from other quaternary ammonium compounds. Unlike most quaternary ammonium compounds, including those that are currently employed as disinfectants, L-carnitine contains functional groups that increase its overall hydrophilicity (Figure 2). Despite slight differences in structure, it can be supposed that L-carnitine’s antimicrobial properties result from the same general mechanism of action as related compounds (i.e. disruption of membrane and protein structures).

There is an urgent need for novel antimicrobial agents. The data presented in this paper strongly suggests that L-carnitine has potential as an effective antimicrobial against Salmonella.
Acknowledgments

We would like to extend our appreciation to Dr. Roy Mosher and Dr. Kathleen Bobbitt of the Department of Biological Sciences at Wagner College for their input and guidance in the completion of these experiments.

Abstract

Manganese (Mn) is an essential metal that at excessive levels in brain causes Manganism, a condition similar to Parkinson's disease. Previously we showed that Mn had a neurotoxic effect on the dopaminergic, but not serotonergic, innervation of the lateral ciliated cells in the gill of the Eastern Oyster, *Crassostrea virginica*. While the mechanism of action of Mn toxicity is not completely understood, studies suggest that Mn toxicity may involve mitochondrial damage and resulting neural dysfunction in the brain's dopaminergic system. In this study we utilized micro-batch chambers and oxygen probes to measure oyster gill mitochondrial respiration in the presence of Mn and potential Mn blockers. The addition of Mn to respiring mitochondria caused a dose dependent decrease in mitochondrial O₂ consumption. Pretreating mitochondria with calcium disodium EDTA (caEDTA), p aminosalicylic acid (PAS) or acetylsalicylic acid (ASA) before Mn additions, provided full protection against the toxic effects of Mn. While mitochondrial pretreatment with any of the 3 drugs effectively blocked Mn toxicity, none of the drugs tested was able to reverse the decrease in mitochondrial O₂ consumption seen in Mn treated mitochondria. The study found that high levels of Mn had a toxic effect on gill mitochondrial O₂ consumption and that this effect could be blocked by the drugs caEDTA, PAS and ASA. *C. virginica* continues to be a good model with which to investigate the mechanism that underlies manganese neurotoxicity and in the pharmacological study of drugs to treat or prevent Manganism.

Introduction

Manganese is an element present in all animal tissues and required as an enzyme cofactor or activator for numerous reactions of metabolism. While essential in trace amounts, excessive manganese exposure can result in toxic accumulations in human brain tissue and resulting extrapyramidal symptoms similar to those seen in patients with Idiopathic Parkinson's disease. This Parkinson-like neurological condition first described in 1837 in two manganese ore-crushing mill workers has been referred to as Manganism. Inhalation of manganese from the atmosphere is believed to be the primary cause of manganese toxicity. In addition to mining and manganese ore processing, high levels of airborne manganese are possible in a number of other occupational settings, including welding, dry battery manufacture, and use of certain organochemical fungicides like Maneb. More recently, questions are being asked about the safety of ambient manganese in the general population and there is a growing concern that chronic low-level occupational or increased environmental exposure to manganese may be a contributing factor in a variety of neurological conditions including the high numbers of people diagnosed with Parkinson's disease in the United States and elsewhere. Although manganese toxicity has been recognized for some time the primary mechanism underlying its neurotoxic effects remains elusive. Clinically, Manganism resembles Idiopathic Parkinson's disease, a dopaminergic cell disorder. Symptoms common to both disorders include gait imbalance, rigidity, tremors and bradykinesia, suggesting a similar etiology of neuronal damage in the substantia nigra with a resulting deficiency of the neurotransmitter dopamine for the striatum. However, compared to Parkinson's, there are some differentiating features seen with Manganism including symmetry of effects, more prominent dystonia, a characteristic cock walk, an intention rather than resting tremor, earlier behavioral and cognitive dysfunction, difficulty turning, and a poor response to Levodopa suggesting different or more extensive damage in the basal ganglia or to the dopaminergic system. Human and animal studies have shown
that toxic exposure to manganese results in metal accumulations in various areas of the basal ganglia and dysfunction of cells of both the striatum and the globus pallidus. Manganese selectively targets dopaminergic neurons in the human basal ganglia and decreases dopamine levels in the striatum. Considering the clinical similarities between Manganism and Parkinson’s Disease, and the fact that manganese accumulates in brain regions rich in dopaminergic neurons, it has long been suggested that manganese neurotoxicity involves a disruption in dopaminergic neurotransmission.

While the cellular and molecular mechanism of manganese toxicity remains unclear, evidence suggests that exposure to manganese or manganese containing compounds induces oxidative stress-mediated dopaminergic cell death, which is in agreement with current theories on oxidative stress as a mediator of neuronal death in Parkinson’s disease and other neurodegenerative diseases. When in excess, manganese has been shown to raise levels of reactive oxygen species (ROS).

Dopamine, serotonin and other biogenic amines are present in the nervous tissue and gill of the Eastern Oyster, *Crassostrea virginica*. The nervous system innervation of the lateral ciliated cells in the gill of *C. virginica* is composed of a cilio-excitatory serotonergic system and a cilio-inhibitory dopaminergic system. *C. virginica* are sedimentary animals known to accumulate metals in their tissues from waters where they reside. The Environmental Protection Agency (EPA) lists them as test animals for studying marine pollutants. Since *C. virginica* provides a relatively simple system with a serotonergic-dopaminergic innervation component that directs an observable and measurable physiological response, this system can be useful in investigating the mechanisms that underlie both manganese neurotoxicity and other dopaminergic cell disorders.

Previously we showed that manganese had a neurotoxic effect on the dopaminergic, but not serotonergic, innervation of the lateral ciliated cells in the gill of *C. virginica* and that *C. virginica* treated with manganese also had lowered endogenous dopamine levels in the gill, cerebral ganglia and visceral ganglia. We showed that the loss of endogenous dopamine could be prevented by co-treating the animals with PAS (p-aminosalycilic acid), a drug that has recently been shown as a successful therapeutic agent for Manganism, but the mechanism of PAS action is unclear. In other experiments, adding PAS or the metal chelator EDTA to oyster gill blocked the neurotoxic effects of manganese on the dopaminergic innervation of the gill lateral ciliated cells.

The present study sought to investigate the effects of manganese on gill mitochondrial respiration. Preliminary work in our lab suggested that manganese reduced gill mitochondrial respiration in *C. virginica*. We also sought to test potential drugs such as EDTA, PAS and ASA (acetylsalicylic acid ) to determine if they would have a blocking effect on manganese toxicity on mitochondrial respiration.

### Materials and Methods

Adult oysters *C. virginica* of approximately 80 mm shell length were obtained from Frank M. Flower & Sons oyster farm in Oyster Bay, NY. Animals were transported on ice to Medgar Evers College within 2 hours of collection and placed in recirculating aquaria with artificial seawater (Instant Ocean, Aquarium Systems Inc., Mentor, OH) at 16-18°C, specific gravity of 1.024 ± 0.001 and pH of 7.8 ± 0.2. Animals were used in the experiments within one week of arriving in the lab. Each animal was tested for health prior to experimentation by the resistance it offered to being opened. Animals that fully closed in response to tactile stimulation and required at least moderate hand pressure to being opened were used for the experiments.

PAS and ASA were obtained from Sigma-Aldrich, St. Louis, MO. All other chemicals were obtained from Fisher Scientific, Pittsburgh, PA. Mitochondria were isolated from oyster gills. The isolation buffer consisted of 540 mM glycine, 250 mM sucrose, 2 mM EDTA, 20 mM Tris-HCl, pH 7.4, and 0.2% bovine serum albumin (BSA, essentially fatty acid free). For each experimental trial, the gills from one animal were removed, blotted dry, weighed and placed in 10 ml of ice cold isolation medium. The tissue was homogenized with five passes of a Potter-Elvehjem homogenizer equipped with a loosely fitting Teflon pestle. The homogenate was centrifuged at 4°C for 10 min at 600 X g in a Sorvall RC5B centrifuge to remove the nuclear pellet. The supernatant was centrifuged at 4°C for 20 min at 10,000 X g to pellet the mitochondria. The resulting mitochondrial pellet was washed twice with ice-cold EDTA-free isolation buffer to minimize binding by the chelator and resuspended...
in 2 ml of ice cold EDTA-free isolation buffer. Oxygen uptake by mitochondria was measured in a Micro-Biological Oxygen Monitor with a 600 μl microbatch chamber (YSI, Yellow Springs, OH). Continuous data acquisition was made using a DI-700 Data Acquisition System (DATAQ Instruments, Inc., Akron, OH). Temperature in the mitochondrial respiration chamber was maintained constant at 20°C using a Haake water circulator. The microbatch chamber was filled with respiratory buffer (0.25 mM succinate, 0.05 mM ADP, 5 mM MgCl₂, 10 mM K₂HPO₄, 540 mM glycine, 250 mM sucrose, 20 mM Tris-HCl, pH 7.4, 0.2% BSA) and allowed to equilibrate. After the baseline was stable for 5 minutes an aliquot (100 μl) of isolation medium containing mitochondria was added to the chamber and basal mitochondrial respiratory rates (state 3) were measured. After 10 minutes, aliquots (20 μl) of Mn, caEDTA, PAS or ASA were added to the chamber to determine their effects on respiratory rates. N ranged from 5-22 and statistical analyses were determined by ANOVA with Tukey post test.

**Results**

The basal oxygen utilization rate for isolated mitochondria from 22 gill samples was 6.18 ± 0.65 μLO₂/hr/gm. Figure 1 illustrates results of a typical run. The baseline is the equilibration period without mitochondria. The steady downward slope after mitochondrial addition demonstrates oxygen consumption of respiring (state 3) mitochondria. Adding manganese (1 mM) decreased the magnitude of the slope as a result of a decreased oxygen consumption. Figure 2 shows that manganese causes a dose dependant decrease in mitochondrial O₂ consumption. Adding up to 1 mM manganese caused a 60% drop in mitochondrial oxygen consumption. Higher doses resulted in greater decreases.

Figures 3a, 4a and 5a show the effects of adding 1 mM of PAS, ASA and caEDTA, respectively, to the microbatch chambers prior to 1 mM manganese additions. None of the drugs had significant effects of their own on basal mitochondrial oxygen consumption. However, each drug fully blocked the toxic effects of manganese on mitochondrial oxygen consumption under the conditions of the experiments. Each of the figures show that when the drug was added prior to manganese there was no significance difference between basal and manganese treated mitochondria.
Mitochondrial $O_2$ Consumption
Effects of 1 mM PAS Followed by 1 mM Mn

Fig. 3a. Effects of PAS on mitochondrial oxygen consumption when applied before manganese. Statistical analysis was determined by ANOVA with Tukey post test, $n = 6$.

Mitochondrial $O_2$ Consumption
Effects of ASA Followed by Mn

Fig. 4a. Effects of ASA on mitochondrial oxygen consumption when applied prior to manganese. Statistical analysis was determined by ANOVA with Tukey post test, $n = 5$.

Mitochondrial $O_2$ Consumption
Effects of 1 mM Mn Followed by 1 mM PAS

Fig. 3b. Effects of PAS on mitochondrial oxygen consumption when applied after manganese. Statistical analysis was determined by ANOVA with Tukey post test, $n = 10$, *p<0.01 compared to basal.

Mitochondrial $O_2$ Consumption
Effects of Mn Followed by ASA

Fig. 4b. Effects of ASA on mitochondrial oxygen consumption when applied after manganese. Statistical analysis was determined by ANOVA with Tukey post test, $n = 14$, *p<0.01 compared to basal.
Figures 3b, 4b and 5b show the effects of adding 1 mM of PAS, ASA and caEDTA, respectively, to the microbatch chambers after 1 mM manganese additions. PAS (Fig. 3b) and ASA (Fig. 4b) were ineffective in reversing the toxic effects of manganese when added after manganese. The manganese-induced drop in mitochondrial oxygen consumption continued to decrease despite the additions of PAS or ASA. When caEDTA was added after manganese (Fig. 5b), it did not reverse the toxic effects of manganese, but in contrast to PAS and ASA, caEDTA did prevent any further drop in oxygen consumption.

Discussion

Manganese is a trace element in animal systems required for normal carbohydrate, lipid, amino acid and protein metabolism, as well as a required cofactor for various antioxidant enzymes such as mitochondrial superoxide dismutase\textsuperscript{1,61}, however high levels can cause the neurodegenerative disorder known as Manganism\textsuperscript{2-5}. While the cellular and molecular mechanism of manganese toxicity remains unclear, several lines of evidence suggest that exposure to manganese or manganese-containing compounds induces oxidative stress-mediated dopaminergic cell death\textsuperscript{46,62,63} which is in agreement with current theories on oxidative stress as a mediator of neuronal death in Parkinson’s disease and other neurodegenerative diseases\textsuperscript{48,54-67}.

Dopaminergic neurons and dopamine-rich areas of the brain are particularly vulnerable to oxidative stress, because the enzymatic and non-enzymatic metabolism of dopamine can generate reactive oxygen species and various neurotoxic catecholamine metabolites such as 6-hydroxydopamine\textsuperscript{66,68-71}. Oxidative stress is also suspected of being a factor in 1-methyl-4-phenyl-1,2,3,6-tetrahydopyridine (MPTP)-induced Parkinson’s disease because transgenic mice who overexpressed copper/zinc superoxide dismutase were protected from the dopaminergic neuronal degeneration caused by MPTP exposure\textsuperscript{73}.

Previous work of our lab showed that manganese reduced dopamine levels in the ganglia and innervated tissues of \textit{C. virginica} and disrupted the dopamine innervation of the lateral gill cilia\textsuperscript{58,59}. We now show that manganese has a deleterious effect on \(O_2\) utilization in gill mitochondria of \textit{C. virginica}.

This study also provides evidence of the protective actions of three drugs, PAS, ASA and caEDTA, as potential manganese blockers with respect to mitochondrial respiration. EDTA is a well known metal chelator and caEDTA has been used in chelation therapy of various metal poisoning conditions, including mercury and lead\textsuperscript{73}. PAS and ASA are structurally related chemicals with anti-inflammatory properties. Jiang \textit{et al.} speculated that the mechanism of action of PAS in alleviating Manganism may be due to its anti-inflammatory ability or its ability to chelate manganese\textsuperscript{60}. ASA is known to chelate iron\textsuperscript{74}, and may have manganese chelating abilities as well. As seen in this study, both PAS and ASA effectively blocked the toxic effects of manganese when applied prior to manganese, but neither
prevented further toxic effects of manganese on mitochondrial oxygen consumption when applied after manganese. Only caEDTA was able to prevent further toxicity when applied after manganese.

The present study demonstrates that C. virginica can be used to investigate the mechanism that underlies manganese neurotoxicity, and may also serve as a model in the pharmacological study of drugs to treat or prevent Manganism and perhaps other dopaminergic cell disorders. The toxic effects of manganese on oyster mitochondria and the protection by PAS, ASA and caEDTA may be of significance in understanding the mechanism of actions of manganese in causing Manganism and possible therapeutic treatments.

Acknowledgments

We wish to thank Frank M. Flower and Sons Oyster Farm, Oyster Bay, NY for supplying oysters. This work was supported in part by grants 2R25GM06003 of the Bridge Program of NIGMS, 0516041071 of NYSDOE and 0622197 of the DUE Program of NSF.

CALL FOR NOMINATIONS

The terms of office for the following positions will be up
for reelection to serve on the
Year 2011-2012 Executive Board

Vice-President
Treasurer
Recording Secretary
Members-at-Large, 2 positions

The duties of these officers will involve attending all Executive Board meetings in addition
to specific duties as described below:

The Vice President will establish and serve as chairperson of the Advisory Council. In the
event the President is no longer able to serve, the Vice President will automatically succeed
to the presidency for the remainder of the term.

The Treasurer of the Association is responsible for the preparation of an annual fiscal
report, processing of dues, preparing regular financial reports for the Executive Board
meetings, income tax reports, and other duties usually pertaining to this office.

The Recording Secretary shall record Board Members who are present, absent, or excused
from Executive Board meetings and shall distribute the minutes of the Executive Board
meetings, the annual business meeting, and any other officially sanctioned meetings as
advised by the Executive Board. The Recording Secretary is responsible for Election
Committee duties as stated in Article VIII - of these Bylaws.

The Members-at Large shall chair committees (Articulation, Exhibition, etc.) and handle
other assignments as directed by the Executive Board.

Normally, each candidate for Vice-President, Recording Secretary and Treasurer should
have been a Member-at-Large for at least one term and each candidate for Member-at-Large
should have attended at least one Annual Conference.

DEADLINE FOR NOMINATIONS is October 15, 2011

If you are interested in running for office (or wish to nominate anyone else), please send a letter of
nomination to:

Dr. Margaret A. Carroll
Biology Department
Medgar Evers College
1638 Bedford Ave
Brooklyn, NY 11225
Purpose

To provide investigative research support for undergraduate students working under the supervision of faculty who are current members of MACUB. Awards Applications will be evaluated and awards granted based on the scientific merit and overall quality of the proposed research experience.

1. Four grants of $500 each will be awarded annually (provided by BC).
2. Complimentary registration for the annual fall conference of MACUB and membership in MACUB for student research grant awardees (provided by MACUB).

Eligibility

1. Only undergraduate students working under the supervision of faculty who is a current member of MACUB may apply.
2. Undergraduates who are graduating seniors must plan to complete their research prior to graduation.
3. A student is only eligible to receive one award.

Requirements

1. Student research grants may be used to support scientific investigation in any field of biology.
2. Funding may be used to purchase equipment or supplies required for the proposed project, and/or travel to and from a research location.
3. Grant winners are required to present the results of research supported by this award at the MACUB annual fall conference following the year of the award.
4. Institutional support is required. This may include research supplies, travel expenses, in-kind matches, and other forms of support.
5. All application materials must be submitted on-line at http://www.macub.org by February 28, 2012 and all applicants will receive notification of award status by March 15, 2012.
You are invited to participate in the 44th Annual Fall MACUB Conference

Member Presentations

Members wishing to make a 2011 Member Presentation (20 min) to discuss the results of research or share ideas, should contact

Dr. Carolyn S. Bentivegna
at Caroyn.Bentivegna@shu.edu or 973-761-9044

Student Poster Presentations

Students wishing to give a 2011 Poster Presentation should submit their abstracts (300 word limit) on-line at the MACUB web site (www.macub.org)

If you have any questions contact Poster Co-Chairs

Dr. Edward Tall
Edward.Tall@shu.edu or 973-275-2069

or

Dr. Gerald Ruscingno
Gerald.Ruscingno@shu.edu or 973-761-9044
Student Membership

We encourage your students to become Associate Members in MACUB. Many of them will go on to graduate and professional schools. Their membership, participation and attendance at conferences such as these can enhance the experiences they include on their applications and discuss during interviews.
